Abstract. The development of applications based over vehicular networks, such as road safety, environmental information etc. require a complete testbed platform for research and evaluation. Such a platform will be provided by NITOS[1] testbed, that will include nodes mounted on cars and fixed nodes of the testbed operating as road side units (RSU). Besides the wireless infrastructure, there will be several sensors regarding the environmental conditions and the vehicle. These will gather measurements about air conditions and GPS data such as position and speed and will be collected in a central database, where the experimenter will be able to depict them in a Google map.

Keywords: Vehicular Network, Delay Tolerant Network, 802.11p, Sensors, Testbed, NITOS, NITlab, Wireless.

1 Introduction

Todays wireless communications testbeds, tend to expand their infrastructure to dynamic deployments, such as mobile and vehicular environments. In the presence of this scope, NITOS is being extended to incorporate nodes mounted on vehicles. Furthermore, we enhance the nodes' capabilities with a sensors framework, based on microcontroller boards. Testbed's users will be able to collect measurements regarding the environmental conditions, the vehicle's trajectory and the vehicle's internal status (e.g. fuel consumption, velocity etc.). These measurements include temperature, humidity and CO2 indications. Measurement points will be localized according to the GPS coordinates and they will consist of data, concerning the vehicle's speed, elevation and position.

The methodology that will be used to collect sensors measurements, will be incorporated into an OML framework[2], which is currently available in

* The research leading to these results has received funding from the European Community's Seventh Framework Programme (FP7/2007-2013) under grant aggreement n^{o}288254 (REDUCTION).

NITOS testbed to the experimenters, as a framework that collects measurements. The data collected from the sensors will be initially stored locally on the car-mounted node and afterwards, it will be uploaded to the testbed's central database through an RSU.

The above implies a delay tolerant network (DTN), which is achieved through an OML module, named OML-Proxy-Server[3] and acts as local buffer before the measurements are being sent to the central OML server of the testbed.

Finally the experimenter will be able to retrieve the database file during the experiment, so he can evaluate the received measurements as soon as they are collected and injected into the database. The network scheme is shown in Figure 1.

2 Network Components

The main components of the vehicular network contain the hardware parts, which are the sensors and the nodes. However, besides the necessary hardware, a bunch of software programs are used to collect measurements using OML. Additionally a web interface will be available to the experimenter to evaluate the car's route and measurements.

The connection between the car mounted node and the RSU is achieved through a WiFi interface. The communication protocol used for this set up is the 802.11p, using Mikrotik R52 wireless cards.

The RSU will be a static node of NITOS testbed. It will be responsible to forward the received measurements, from the car to the testbed's server, where the data will be stored in a sqlite3[4] database.

Regarding the sensors infrastructure, we exploit Arduino Uno[5] potential, which is a programmable microcontroller board and let us feature the car's node with CO2 2(a), temperature and humidity 2(b) sensors. Additional, a GPS module is connected to the car node and enables measurements like *Latitude, Longitude, Altitude, Speed, Vertical Speed and Direction.*

3 Conclusions and Future Work

In this demo, a vehicular network with multiple sensors and DTN capability is presented as part of the NITOS testbed. Temperature, humidity, CO2 and GPS measurements are collected through an OML framework and stored in a central database. During the experiment a dynamic Google map is created, depicting all the available data contained in the database so far. For future work, we plan to control the network's resources with the OMF[6] framework, which is featured on NITOS testbed for conducting experiments.
